Introduction

Children make mistakes in the interpretation of:

- *He washes him
- He washes himself

In Italian no such errors are made

Differences between Dutch/English and Italian?

Chien, Y. C., & Wexler, K. (1990). Children's Knowledge of Locality Conditions in Binding as Evidence for the Modularity of Syntax and Pragmatics. *Language Acquisition*, 1(3), 225-295.

McKee, C. (1992). A Comparison of Pronouns and Anaphors in Italian and English Acquisition. *Language Acquisition*, 2, 21-54.

Introduction

Italian: 2 types of subject pronouns

- Null subject (\emptyset)
- Overt subject

How much information does a subject hold?

-> How much 'freedom' is there when solving a pronoun?

→ What are the effects of the presence and interpretation of subject pronouns on the processing and interpretation of object pronouns?

Experimental Design

Eye-tracking study looking at pupil size

- 40 Dutch adults
- 120 Stories, audio
- 2 Pictures
- Referent selection task

Conditions

- Pronoun vs. full NP as the **subject**
- Pronoun vs. reflexive as the **object**

Experimental Design

Stories of 3 phrases

- 1 De egel heeft een boomhut gebouwd.
- 2 Afgelopen dinsdag liep de egel met de muis door het bos naar huis,
- 3 - terwijl hij/de egel hem volgde over een donker pad.
- terwijl hij/de egel zich haastte over een donker pad.

Afterwards, a question was asked about one of the characters

Experimental Design

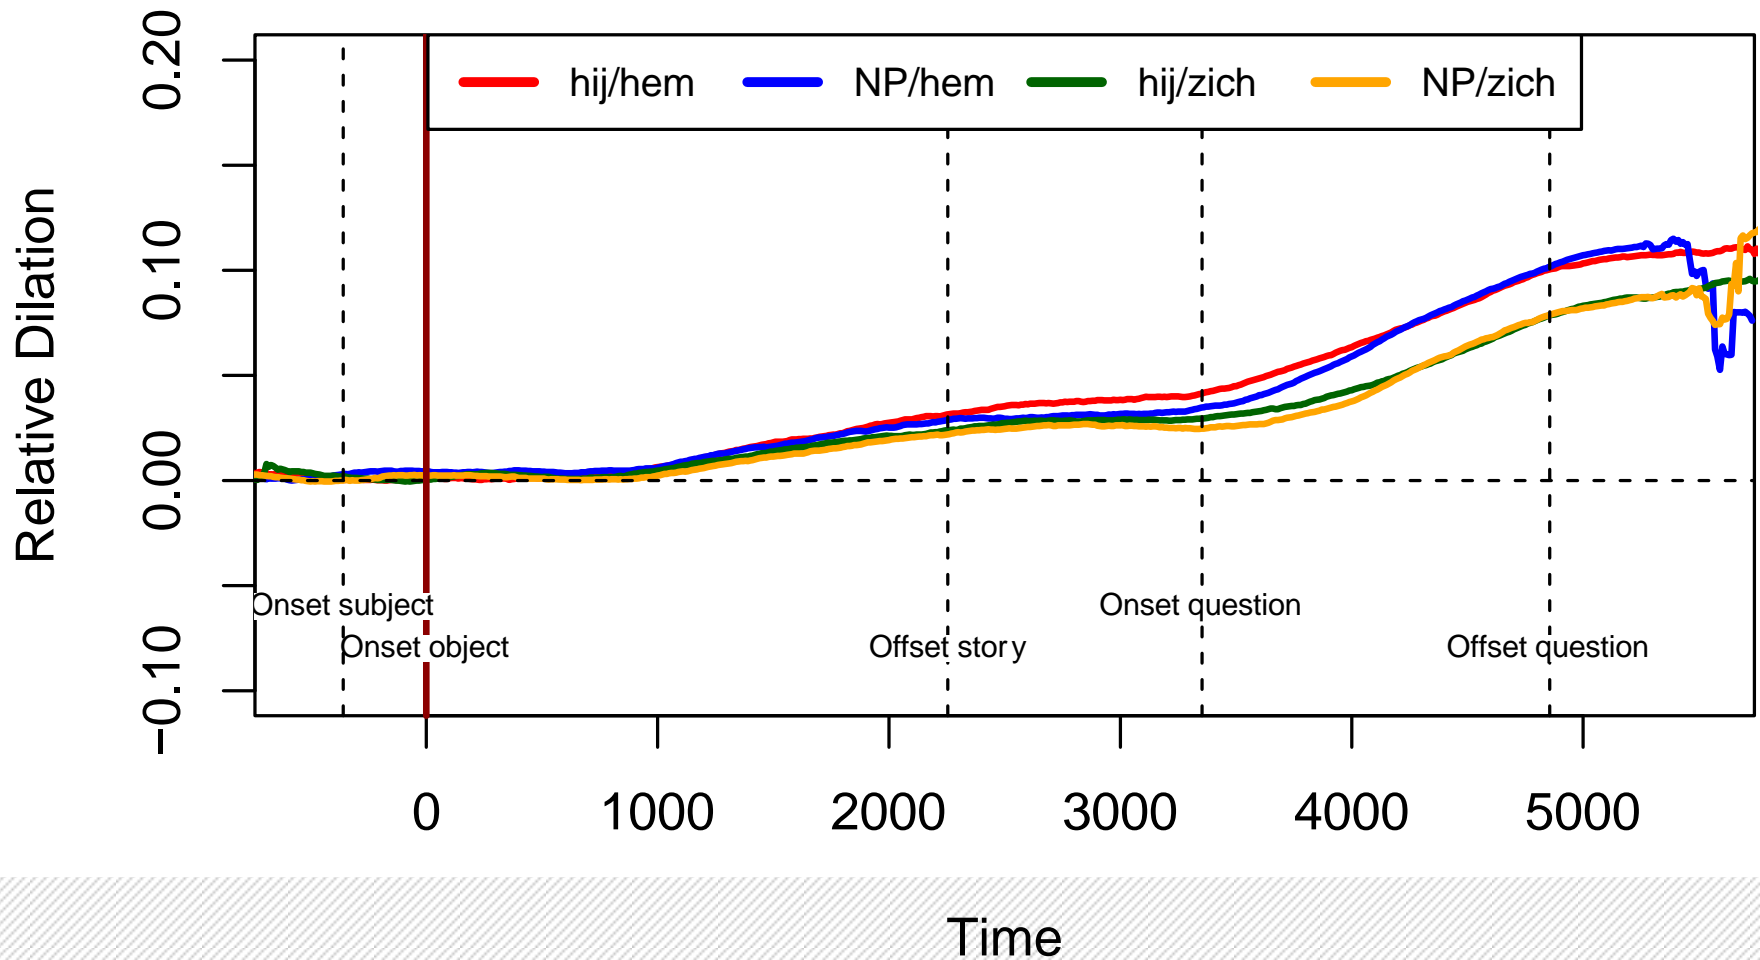

Hypotheses

1. A subject NP is easier to process than 'hij'
2. The object 'zich' is easier to process than 'hem'
3. An object pronoun is more difficult to resolve when following a subject pronoun than when following a subject NP,
i.e. The ambiguity of the subject plays a role in the processing of the object

Results

Results

Linear mixed-effects models (lmer)

- Fixed effects and random effects (mixed effects)
- Useful with repeated measures
- Advantage in dealing with missing values (as opposed to repeated-measures ANOVA)
- Mixed-effects analysis is relatively easy to do and does not require a balanced design (which is generally necessary for repeated-measures ANOVA)

NB: t-values given. We assume $t > 2$ means there is an effect

Results

Testing the subject and object conditions at specific time points with an lmer:

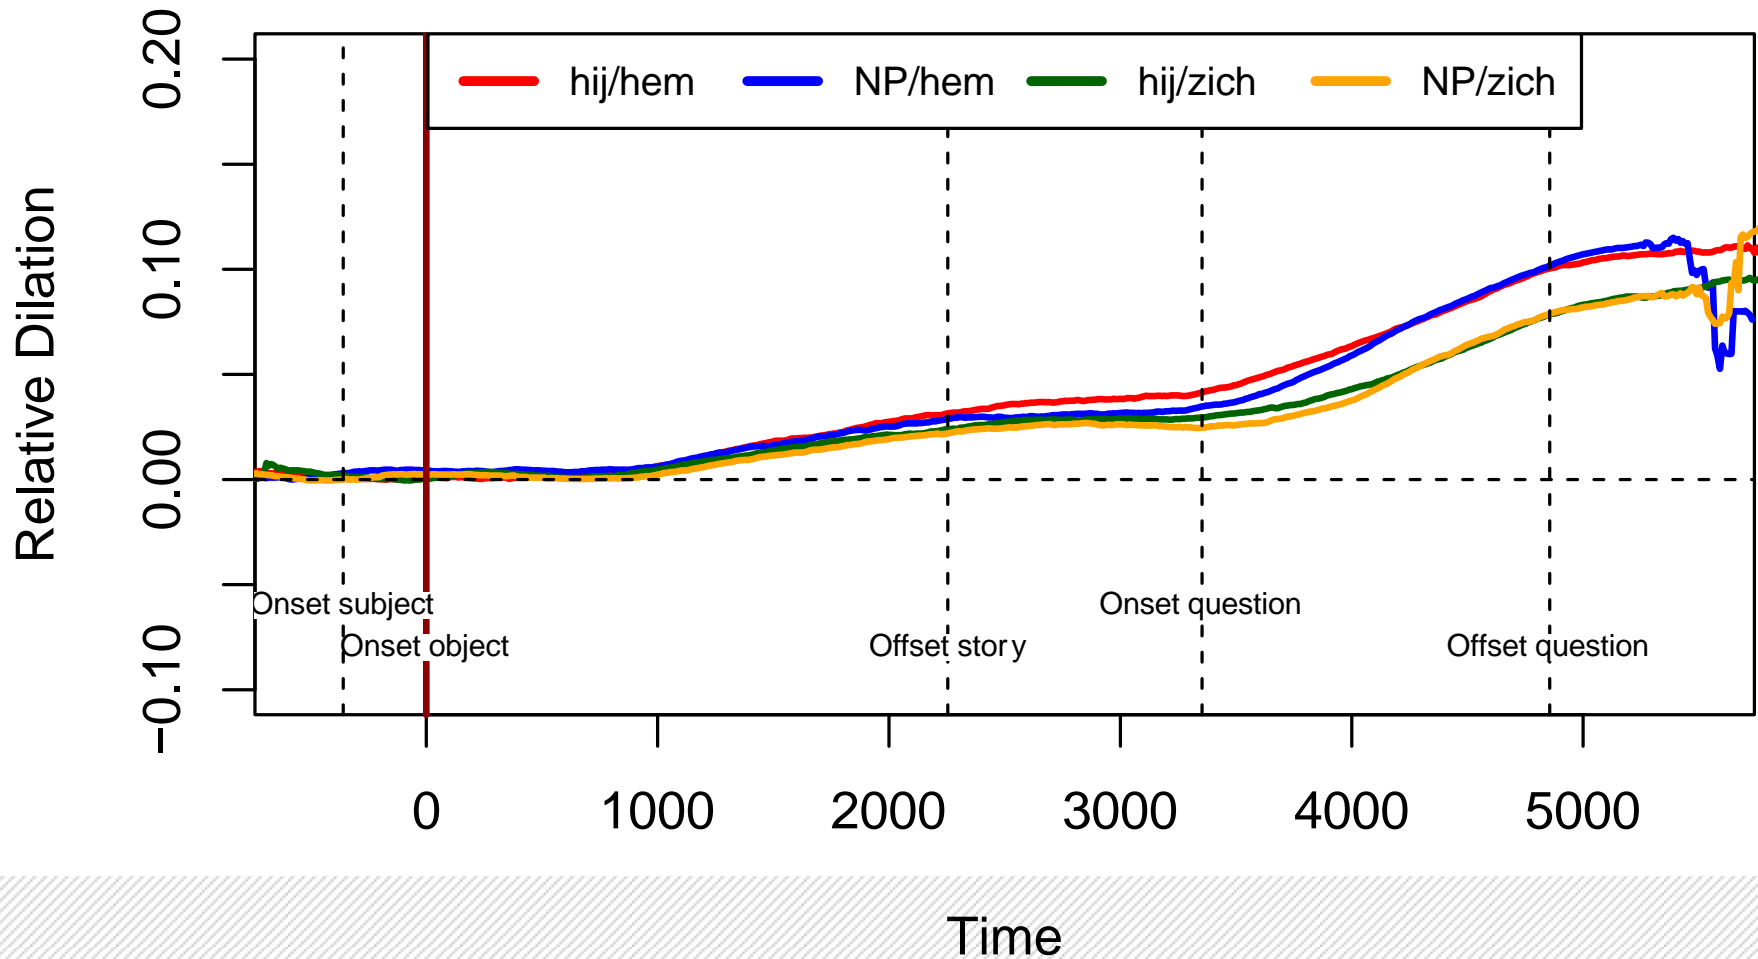

At time after onset object == 2500, no differences between conditions ($t = 1.26$ subject, $t = 1.03$ object)

At time after onset object == 4500: $t = 0.20$ subject, $t = \mathbf{3.90^*}$ object

-> 'hem' more difficult than 'zich'

Results

Results

1000ms after the start of the question:

No difference between question types ($t = 0.78$)

Difference between objects (**$t = 2.45$**)

No difference between subjects ($t = 0.28$)

Results

Accuracy:

| | NP/hem | NP/zich | hij/hem | hij/zich |
|---|--------|---------|---------|----------|
| 0 | 33 | 26 | 92 | 61 |
| 1 | 1167 | 1174 | 1108 | 1139 |

- NP easier than 'hij' (**p < 0.001**)
- 'zich' easier than 'hem' when the question refers to the subject (**p = 0.002**)

RT:

- Questions referring to the subject are answered faster (**t = -3.49**)
- Questions with an NP are answered faster (**t = -4.24**)
- 'zich' faster than 'hem' when the question refers to the subject (**t = -2.00**)

Results

Summary so far:

1. A subject NP is easier to process than 'hij'
 - > found in RT and ACC but not DIL
2. The object 'zich' is easier to process than 'hem'
 - > partially found in RT, ACC and DIL
3. An object pronoun is more difficult to resolve when following a subject pronoun than when following a subject NP
 - > GAMs

Results

Generalized additive models (GAMs)

- the story examined over time
 - linear predictor is specified in terms of a sum of non-parametric smooth functions of predictor variables
 - Overfitting prevented by penalties on smoothing
 - Can be used on eye-tracking data, EEG, fMRI
- 1 filter out the trend
 - 2 fit the residuals for each condition
 - 3 compare different models

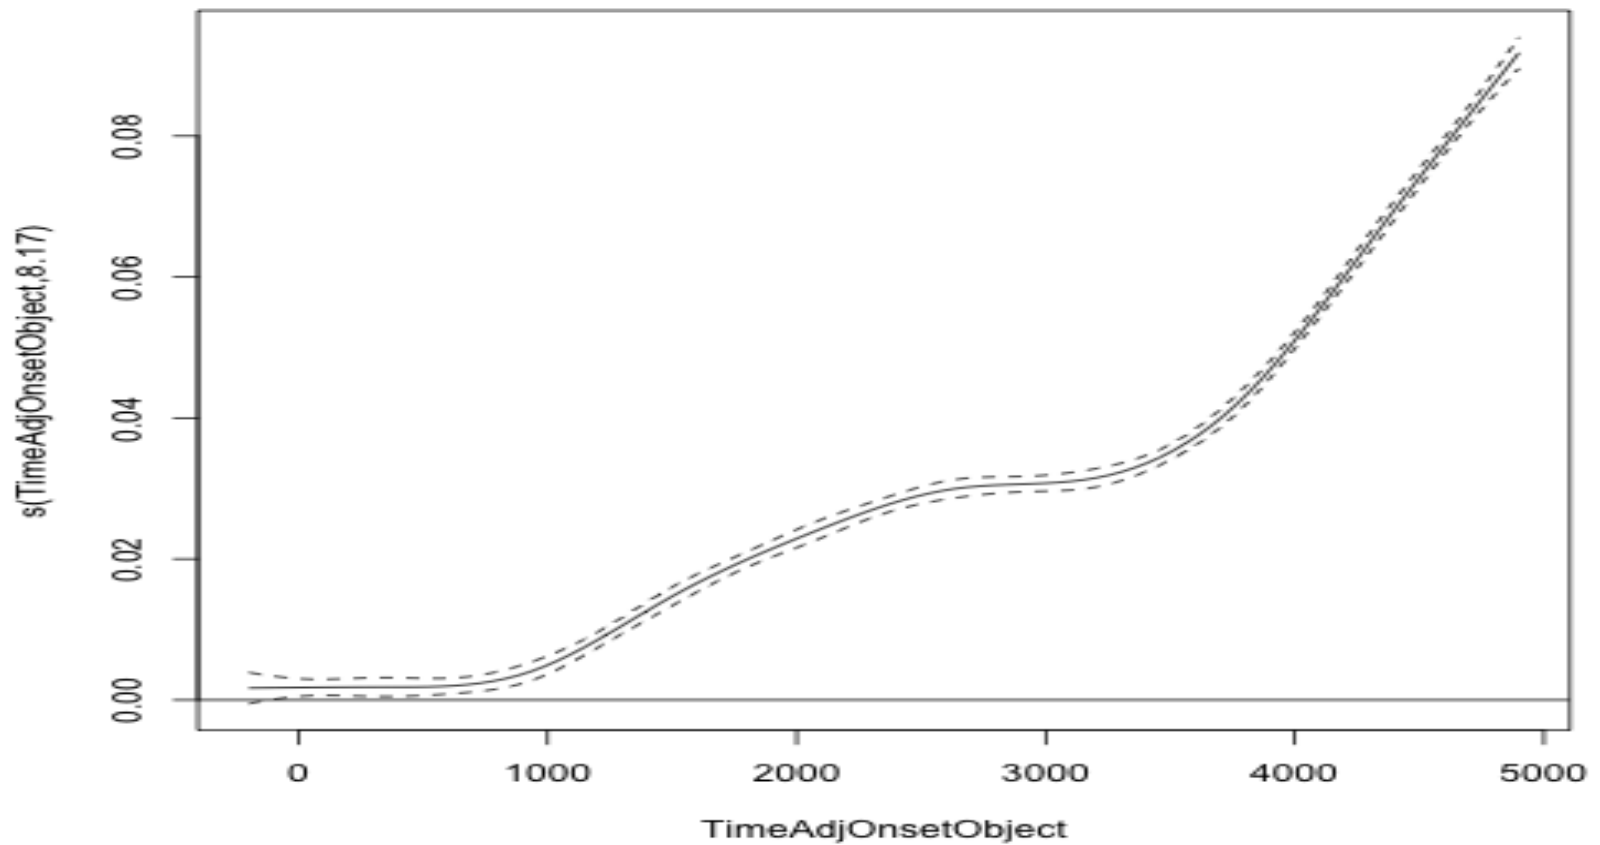

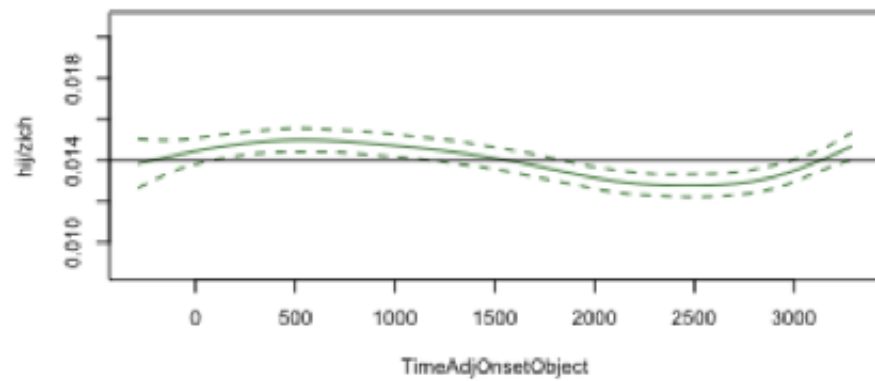

Results

Results

Results

Anova:
 Full model vs.
 model **without**
 the the object
 condition

Full model is better
 ($p < 0.001$)

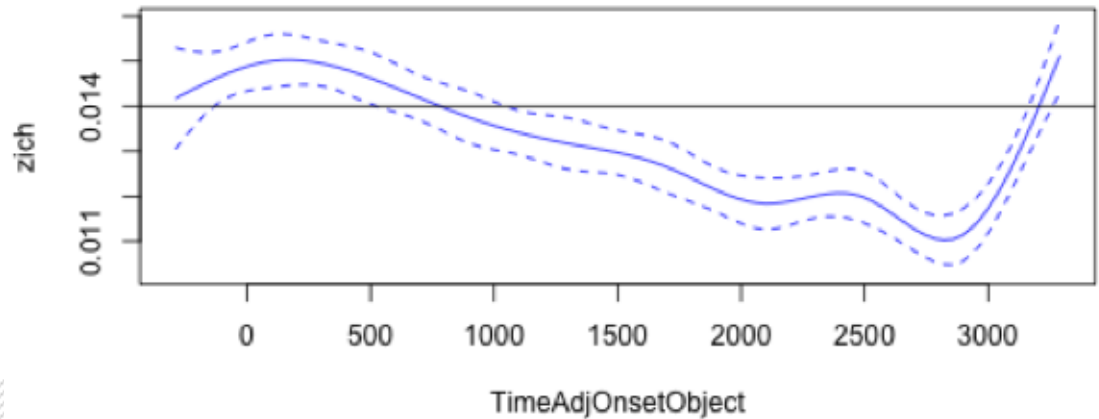

Results

Anova:
 Full model vs.
 model **without**
 the the subject
 condition

Full model is better
 (**$p < 0.001$**)

Results

Interactions between all conditions found (**p = 0.01**),
so the results were **not just additive**.

This is important to be able to say something about the
influence of one condition on the other.

Results summary

1. A subject NP is easier to process than 'hij'
-> found in RT, ACC and GAMs, but not DIL
2. The object 'zich' is easier to process than 'hem'
-> partially found in RT, ACC and DIL, found in
GAMs
3. An object pronoun is more difficult to resolve when
following a subject pronoun than when following a
subject NP
-> interaction found in GAMs

Conclusions

More ambiguous/free pronouns are more difficult to process ('hem' vs. 'zich', 'hij' vs. NP)

Ambiguity of the subject influences processing of the object
